I am a DIY audio effects builder, mainly to use in my guitar playing. Up to now I simply copied circuits on the net, but I'd like to go a bit further in understanding. My first obstacle is ... a capacitor! I found out that, in the effects I build, the input signal (from my guitar) goes to a capacitor, and from there to the rest of the circuit.

The US Army asked Bell Laboratories to design a machine to assist in testing its M-9 gun director, a type of analog computer that aims large guns to their targets. Mathematician George Stibitz recommends using a relay-based calculator for the project. The result was the Relay Interpolator, later called the Bell Labs Model II.

Power source. In the first experimental telephones the electric current that powered the telephone circuit was generated at the transmitter, by means of an electromagnet activated by the speaker's voice. Such a system could not generate enough voltage to produce audible speech in distant receivers, so every transmitter since Bell's patented design has operated on a direct current supplied

The "something" is often an electric bell: a little dating from the early 20th century, uses two interlinked circuits. The first one, shown in red, connects a pressure switch (green, 12), battery (10), and lamp (yellow, 21). How a rotary doorbell switch works. This design is by David Brown, an inventor from Chicago, and dates

from 1935.
